NETRUNNERMERC

PERSONAL PROJECT

DOCUMENTED AND DEVELOPED BY [netrunnerMerc](#)

2026

ACKNOWLEDGEMENTS

I was highly inspired by the game Cyberpunk 2077 for the development of this project. This project uses AI and has used Claude for its development.

ABSTRACT

Questlines is a Cyberpunk 2077-inspired task management application that turns everyday responsibilities into atmospheric contracts. Built with a FastAPI backend, SQLite persistence, and a vanilla HTML/CSS/JavaScript frontend, it lets users create quests, assign fixers or NPCs, classify work as main jobs, side gigs, or personal missions, and track active, completed, or failed status. An XP and leveling system rewards completed contracts while deducting progress when missions are reactivated. The AL-107 assistant integrates Hugging Face chat completions to generate quest titles, gritty descriptions, operational briefings, status messages, and contextual chat replies based on the player's current workload. A PIN-protected API, fixer network view, mission archive, animated contract acceptance flow, audio cues, and mobile-friendly browser access create a focused productivity tool wrapped in an immersive Night City interface. The project demonstrates lightweight full-stack design, gamification, and AI-assisted narrative framing for personal task tracking and motivation without requiring a complex deployment pipeline setup.

LAYOUT

ADDITIONAL INFORMATION

Benefits

Questlines makes task management more engaging by turning ordinary work into game-like missions with titles, descriptions, XP, levels, and completion feedback. Its Cyberpunk-inspired interface gives users a stronger sense of progress and atmosphere than a standard to-do list. The AL-107 assistant adds AI-generated briefings and contextual replies, helping tasks feel more meaningful and organized. The fixer/NPC system also supports grouping tasks by source, person, or theme.

Needs

The project needs a Hugging Face API token to enable AI-generated quest names, descriptions, and AL-107 chat responses. It also needs Python dependencies, a running FastAPI server, and SQLite storage for quests and player progress. For practical use, it requires consistent task entry, status updates, and secure PIN management. Future needs could include stronger authentication, cloud sync, backups, multi-user support, and improved deployment for use across devices.

How Data Is Stored

Questlines stores data locally using a SQLite database named `quests.db` in the backend folder. The backend uses SQLAlchemy models to define two main tables: `quests` and `player`.

The `quests` table stores each task as a quest, including its title, original task text, AI-generated description, NPC or fixer name, quest type, status, XP reward, and creation/update timestamps.

The `player` table stores the user profile, including the player name, total XP, and current level. When a quest is completed, XP is added to the player record; if a completed quest is reactivated, XP is removed.

Data is accessed and updated through FastAPI endpoints, while the frontend communicates with those endpoints using authenticated API requests.

How To Use

This project can be used as a project or you can use it as a fun to do list app. Feel free to add or remove whatever you like.
